Abstract

There must be an abstract of no more than 250 words. One or two sentences providing a basic introduction to the field, comprehensible to a scientist in any discipline.

Two to three sentences of **more detailed background**, comprehensible to scientists in related disciplines.

One sentence clearly stating the **general problem** being addressed by this particular study.

One sentence summarizing the main result (with the words "here we show" or their equivalent).

Two or three sentences explaining what the **main result** reveals in direct comparison to what was thought to be the case previously, or how the main result adds to previous knowledge.

One or two sentences to put the results into a more **general context**.

Two or three sentences to provide a **broader perspective**, readily comprehensible to a scientist in any discipline.

24 Keywords: social cognition, individual differences, gaze cues, psychometrics

Word count: X

Measuring individual differences in the understanding of gaze cues across the lifespan

conclusion

72 Introduction

- Idea for an opener :)
- Developmental psychology is facing a dilemma: many research questions are
- questions about individual differences, yet, there is a lack of tasks to reliably measure these
- ⁷⁶ individual differences. For example
- individual differences in developmental psychology
 - reliable tasks, variation needed, more trials
- existing tasks for social cognition: wellman
- goal of the current project

Design of our balloon finding task

82 Stimuli

78

81

- Our newly implemented balloon finding task displays cartoon-like stimuli that are
 engaging for children and adults alike. An animal character (i.e., agent; sheep, monkey, or
 pig) is placed centrally in a window. A balloon (i.e., target; blue, green, yellow, or red) is
 located in front of them. The target then falls to the ground. At all times, the agent's gaze
 tracks the movement of the target. That is, the pupils and iris of the agent move in a way
 that their center aligns with the center of the target. Participants are then asked to locate
 the target's position on the screen.
- To keep participants engaged and interested, the presentation of events is
 accompanied by cartoon-like sounds. Each trial starts with an eye-blinking sound, while
 pupils and iris get slightly enlarged and change in opacity for 0.3 sec. The landing of the
 target is accompanied by a tapping sound. Once the target landed, the instructor's voice
 asks "Where is the balloon?" After the response is registered, a short plop sound plays and

a small orange circle confirms the participants' location choice. If no response got registered within 5 secs after the target landed, an audio prompt reminds the participant to respond.

97 Trials

Before participants advance to the test trials, there are four training trials. In the 98 first training trial, participants have full visual access to the target flight and the target's 99 end location and are simply asked to click on the visible balloon. In the second and third 100 training trials, participants have partial visual access: they witness the target flight but 101 cannot see the target's end location. They are then asked to click on the invisible balloon, 102 i.e., the location where they saw the target land. In test trials, participants have no visual 103 access to the target flight nor the end location. Participants are expected to use the agent's 104 gaze as a cue to locate the target. The first trial of each type comprises a voice-over 105 description of the presented events. After these four training and audio guided trials, 106 participants receive 15 test trials. The complete sequence of four training trials and 15 test 107 trials can be administered within 5-10 minutes testing time. 108

109 Study versions

We designed two study versions which can be chosen according to the researchers' 110 need: there is a continuous hedge version and a discrete box version. The versions use the 111 same first training trial and then differ in the two consecutive training trials and the test 112 trials. In the hedge version, participants have to indicate their estimated target location 113 directly on a hedge (i.e., hedge version). Here, the dependent variable is imprecision, which is defined as the absolute difference between the target's true x coordinate and the x 115 coordinate of the participant's click. In the box version, participants are asked to click on a box that hides the target. Researchers have the choice of how many boxes are shown: one 117 up to eight boxes can be displayed as potential hiding locations. Here, we use a categorical 118 outcome (i.e., which box was clicked) to calculate the proportion of correct responses. Note 119

that in the test trials of both study versions, the target flight is covered by a hedge. In the hedge version, the hedge then shrinks to a minimum height required to cover the target's end location. In the box version, the hedge shrinks completely. The boxes then hide the target's final destination.

124 Randomization

All agents and target colors appear equally often and are not repeated in more than two consecutive trials. The randomization of the target end location depends on the study version. In the *hedge* version, the full width of the screen is divided into ten bins. Exact coordinates within each bin are then randomly generated. In the *box* version, the target randomly lands in one of the boxes. As with agent and color choice, each bin/box occurs equally often and can only occur twice in a row.

31 Implementation

Our balloon finding task is presented as an interactive web-app. This way, the task is
portable across devices and web browsers and does not require any installation. A great
advantage of online testing is that our testing procedure is standardized across participants.
Study instructions were pre-recorded and no interaction with the experimenter is necessary
during the study. The code is open-source (https://github.com/ccp-eva/gafo-demo) and a
live demo version can be found under: https://ccp-odc.eva.mpg.de/gafo-demo/.

The web-app was programmed in JavaScript (ECMAScript 2015, i.e., ES6), HTML5, CSS and PHP. For the web-app development, we chose the zero configuration bundler Parcel. It enables a live server for debugging, makes imports easy, and minifies scripts in order to save data storage. For the design of the landing pages, the CSS library Material Components Web (TODO: insert citation) was used. For stimulus presentation, a scalable vector graphic (SVG) composition was parsed. This way, the composition scales according

to the user's view port without loss of quality, while keeping the aspect ratio and relative object positions constant. Furthermore, SVGs allow us to define all composite parts of the scene (e.g., pupil of the agent) individually. This is needed for precisely calculating exact pupil and target locations and sizes. Additionally, it makes it easy to adjust the stimuli and, for example, add another agent to the scene. The GreenSock Animation Platform (GSAP; TODO: insert citation) library was used to animate the movement of single SVG elements.

The web-app generates two file types: (1) a text file (.json) containing meta-data, trial specifications and participants' click responses, and (2) a video file (.webm) of the participant's webcam recording. For our samples described in this paper, we deployed the web-app on servers located in Leipzig, Germany. Data got automatically collected and safely stored on these in-house servers. If no internet connection or server is available, researchers could download a local version of the experiment which stores the generated data automatically on the used device.

158 Data processing

159

160

161

162

166

• workflow server to R, converting coordinate systems We used R [Version 4.1.2; R Core Team (2021)] and the R-package *papaja* [Version 0.1.0.9997; Aust and Barth (2020)] for all our analyses.

Does the balloon finding task induce variation?

Supplements

Adult sample

211

Recruitment. We recruited participants using the online participant recruitment 213 service *Prolific* from the University of Oxford. *Prolific*'s subject pool consists of a mostly 214 European and US-american sample although subjects from all over the world are included. 215 The recruitment platform realises ethical payment of participants, which requires 216 researchers to pay participants a fixed minimum wage of £5.00 (around US\$6.50 or €6.00) 217 per hour. We decided to pay all participants the same fixed fee which was in relation to the 218 estimated average time taken to complete the task. Prolific distributed our study link to 219 potential participants, while the hosting of the online study was done by local servers in the Max Planck Institute for Evolutionary Anthropology, Leipzig. Therefore, study data was saved only on our internal servers, while *Prolific* provided demographic information of the participants. Participants' Prolific ID was forwarded to our study website using URL 223 parameters. This way, we could match participant demographic data to our study data. 224 The same technique was used to confirm study completion: we redirected participants from 225 our study website back to the *Prolific* website using URL parameters. We used *Prolific*'s 226 inbuilt prescreening filter to include only participants who were fluent in English and could 227 therefore properly understand our written and oral study instructions. 228

Study 1 - Validation hedge version. The aim of Study 1 was to validate the
hedge version of our balloon finding task. The pre-registration can be found here:
https://osf.io/r3bhn. We recruited participants online by advertising the study on *Prolific*.

50 adults participated in the study. One additional subject returned their submission,
i.e., decided to leave the study early or withdrew their submission after study completion.

Data collection took place in May 2021.

235

Participants were compensated with £1.25 for completing the study. We estimated

an average completion time of 6 minutes, resulting in an estimated hourly rate of £10.00.

In average, participants took 05:56min to complete the study.

Participants were required to complete the study on a tablet or desktop. Participation on mobile devices was disabled since the display would be too small and would harm click precision. It was indicated that the study required audio sound.

We stored *Prolific*'s internal demographic information, while not asking for additional personal information.

After clicking the study title, participants were directed to our online study website.

Study 2 - Validation box version. As in study 1, we recruited participants on

Prolific, and employed the same methodology. However, this time we focussed on

validating the box version of the task in an adult sample. Participants were presented with

eight boxes in which the target could land.

50 adults participated in the study. One additional subject returned their submission, i.e., decided to leave the study early or withdrew their submission after study completion. Data collection took place in June 2021.

Participants were compensated with £1.00 for completing the study. We estimated an average completion time of 6 minutes, resulting in an estimated hourly rate of £10.00.

In average, participants took 04:43min to complete the study.

Study 3 - Reliability hedge version. In study 3 and 4, we assessed the
test-retest reliability of our balloon-finding task in an adult sample. The pre-registration
can be found here: https://osf.io/nu62m. We tested the same participants twice with a
delay of two weeks. The testing conditions were as specified in Study 1 and 2. However,
the target locations as well as the succession of animals and target colors was randomized
once. Each participant then received the same fixed randomized order of target location,
animal, and target color. Participants received 30 test trials without voice-over description,

so that each of the ten bins occurred exactly three times.

In addition to the beforementioned prescreening settings, we used a whitelist. *Prolific*has a so-called *custom allowlist prescreening filter* where one can enter the *Prolific* IDs of
participants who completed a previous study. Only these subjects are then invited to
participate in a study. This way, repeated measurements can be implemented, collecting
data from the same subjects at different points in time.

In a first round, 60 participants took part on the first testday. Additional two
subjects returned their submission, i.e., decided to leave the study early or withdrew their
submission after study completion. One additional participant timed out, i.e., did not
finish the survey within the allowed maximum time. The maximum time is calculated by
Prolific, based on the estimated average completion time. For this study, the maximum
time amounted to 41 minutes. For the first testday, participants were compensated with
£1.25. We estimated an average completion time of 9 minutes, resulting in an estimated
hourly rate of £8.33. In average, participants took 07:11min to complete the first part.

Of the 60 participants that completed testday 1, 41 subjects finished testday 2. One additional participant timed out, i.e., did not finish the survey within the allowed maximum time. Participants were compensated with £1.50 for completing the second part of the study. We estimated an average completion time of 9 minutes, resulting in an estimated hourly rate of £10. In average, participants took 06:36min to complete the second part of the study.

Since we aimed for a minimum sample size of 60 subjects participating on both testdays, we reran the first testday with additional 50 participants. Additional seven subjects returned their submission, i.e., decided to leave the study early or withdrew their submission after study completion. Two additional participants timed out, i.e., did not finish the survey within the allowed maximum time. Again, participants were compensated with £1.25 for completing the first part of the study (estimated average completion time 9

minutes, estimated hourly rate of £8.33). In average, participants took 06:51min to complete the first part.

Of the additional 50 participants that completed testday 1, 29 subjects finished testday 2. Again, participants were compensated with £1.50 for completing the second part of the study (estimated average completion time 9 minutes, estimated hourly rate of £10). In average, participants took 06:26min to complete the second part of the study.

Study 4 - Reliability box version. As in study 3, we recruited participants on Prolific, and employed the same methodology. However, this time participants were presented with the box version of the task. Participants received 32 test trials without voice-over description, so that each of the eight boxes occurred exactly four times. As in study 2, we employed eight boxes in which the target could land.

In a first round, 60 participants took part on the first testday. Additional five subjects returned their submission, i.e., decided to leave the study early or withdrew their submission after study completion. For the first testday, participants were compensated with £1.25. We estimated an average completion time of 9 minutes, resulting in an estimated hourly rate of £8.33. In average, participants took 07:33min to complete the first part.

Of the 60 participants that completed testday 1, 41 subjects finished testday 2.

Participants were compensated with £1.50 for completing the second part of the study. We estimated an average completion time of 9 minutes, resulting in an estimated hourly rate of £10. In average, participants took 07:50min to complete the second part of the study.

Since we aimed for a minimum sample size of 60 subjects participating on both
testdays, we reran the first testday with additional 50 participants. Additional eight
subjects returned their submission, i.e., decided to leave the study early or withdrew their
submission after study completion. One additional participant timed out, i.e., did not
finish the survey within the allowed maximum time. Again, participants were compensated

with £1.25 for completing the first part of the study (estimated average completion time 9 minutes, estimated hourly rate of £8.33). In average, participants took 07:37min to complete the first part.

Of the additional 50 participants that completed testday 1, 28 subjects finished
testday 2. Additional three subjects returned their submission, i.e., decided to leave the
study early or withdrew their submission after study completion. One additional
participant timed out, i.e., did not finish the survey within the allowed maximum time.
Again, participants were compensated with £1.50 for completing the second part of the
study (estimated average completion time 9 minutes, estimated hourly rate of £10). In
average, participants took 06:30min to complete the second part of the study.

324 Child sample

Study 1 - Validation Remote and in-person. The validation of our task in a in-person and remote child sample can be found here: https://osf.io/snju6. We chose to have at least 20 data points per cell (i.e. unique combination of data collection mode, study version, and age-group). Across the two data collection modes, a total of 267 children participated. Participants received a small gift as thank you for their participation in the study.

For our in-person supervised testing sample, we went to kindergartens in Leipzig and surroundings that cooperate with the Max Planck Institute for Evolutionary Anthropology. For our remote unsupervised testing sample, families were recruited on a voluntary basis via email from the database of the Max Planck Institute for Evolutionary Anthropology. Children in both sub samples live in Leipzig, Germany or surrounding areas and grow up in an industrialized, urban Central-European context. Information on socioeconomic status was not formally recorded, although the majority of families come from mixed, mainly mid to high socioeconomic backgrounds with high levels of parental education. Written

informed consent was obtained from at least one caregiver prior to testing. TODO: how to
phrase for kiga testing?

Procedure Remote Testing

In the beginning of the online study, families were invited to enter "our virtual 342 institute" and were welcomed by an introductory video of the study leader, shortly 343 describing the research background and further procedure. Then, caregivers were informed 344 about data security and were asked for their informed consent. They were asked to enable 345 the sound and seat their child centrally in front of their device. Subsequently, a brief demographic questionnaire was displayed, asking for (1) the total number of household members, (2) the number of children, (3) age of the other children, (4) whether the child 348 was in day care, and if yes, (5) since when and (6) for how long on an average day. Before the study started, families were instructed how to setup their webcam and enable the 350 recording permissions. Study participation was video recorded whenever possible in order 351 to ensure that the answers were generated by the children themselves. Then, families were 352 guided through the online study with pre-recorded audio instructions. After completion, 353 families received a little crafting / coloring sheet as a small thank-you gift. 354

Depending on the participant's device, the website automatically presents the hedge 355 or box version of the study. For families that use a tablet with touchscreen, the hedge 356 version is shown. Here, children can directly click on the screen themselves to indicate 357 where the target is. For families that use a computer without touchscreen, the website 358 presents the box version of the task. We assumed that younger children in our sample would not be acquainted with the usage of a computer mouse. Therefore, we asked children to point to the screen. Caregivers were then asked to act as the "digital finger" of their 361 children and click on the indicated box. In order to facilitate the translation of children's 362 pointing and caregivers' clicking, we decided to implement this categorical version of the 363 task. 364

369

Our in-person supervised testing sample involved 120 children, including 40 3-year-olds (mean = 41.45 months, SD = 3.85, range = 36 - 47, 22 girls), 40 4-year-olds (mean = 54.6 months, SD = 3.1, range = 48 - 59, 19 girls), and 40 5-year-olds (mean = 66.95 months, SD = 3.39, range = 60 - 71, 22 girls).

Study 2 - Reliability in-person. https://osf.io/xqm73
